Bucuresti, 1957, 169-188

ABSTRACT : Lines evolved from the local Banat sort were obtained by the selection method. Elite cabbage material was grown in hot houses to shorten the periods of selection. The most valuable forms were subjected to chemical analysis for percentage of dry substance, sugar content, raw protein. The analyses established the high economic value of the sorts of white-head cabbage derived. High level agriculture and proper cultivation of seedlings of cabbage made it possible to obtain crops reaching 700 to 880 centers/hectare.

TITLE: The effect of the type of carbon black on vulcanization kinetics and structure of vulcanizates

SOURCE: Kauchuk i rezina, no. 4, 1964, 10-15

TOPIC TAGS: vulcanization, vulcanization kinetics, vulcanizate structure, vulcanizate cross link, vulcanization sulfur binding, butadiene styrene rubber, BSK rubber, natural rubber, carbon black filler, carbon black, rubber fatigue resistance, vulcanizate thermal resistance

ABSTRACT: The authors discuss the effect of various types of carbon black on the formation of cross-links, on the development of sulfur binding in butadiene-styrene and in natural rubber mixtures, and on the thermomechanical and thermo-oxidative resistance of the vulcanizates. The carbon blacks tested included the channel type, the furnace gas type PG-40, and the furnace types KhAF and FIF (from liquid hydrocarbons). The rubber-to-carbon black ratio was 100:50. The concentration of effective cross-links in the vulcanizates was calculated from their maximum swelling in metaxylene. It was found that at 153°C the density of

Card 1/3

ACCESSION NR: AP4034469

the vulcanization network was higher in filled rubbers and that it depended on the nature of the carbon black (the KhAF and FIF induced cross-linking at a much higher rate than other types within the experimental period of up to 280 minutes). The amount of bound sulfur also increased with the progress of vulcanization. It was much higher in filled rubbers, except in those filled with channel carbon black. The carbon blacks from liquid hydrocarbons led in the process of sulfur binding. The filled vulcanizates showed a higher thermomechanical resistance than the nonfilled ones. It was found that carbon black had a deleterious effect on the thermooxidation of natural rubber while enhancing the stability of butadiene-styrene rubber in air at 130°C. These experimental findings were confirmed by factory tests on tire rubbers. It was also determined that natural rubber with KhAF carbon black had a higher fatigue resistance than natural rubber containing channel black as filler. The authors discuss the reasons for the specific behavior of the various carbon blacks. Orig. art. has: 5 charts and 2 tables.

TITLE: An Analysis of Systems of Automation of Scale Cars
(Analiz sistem avtomatizatsii vagon-vesov)

PERIODICAL: 'Stal', 1959, Nr 1, pp 5 - 9 (USSR)

ABSTRACT: In the Krivorozhskiy zavod (Krivoy Rog Works) efforts for the purpose of automating scale cars were in progress even before the war. In the NTMK (Nizhniy Tagil Met. Combine) such efforts have been in progress jointly with the UPI (Urals Polytechnical Institute) from 1948 onwards, in the Dnepropetrovsk Gipromez jointly with the imeni Dzerzhinskogo Works from 1949 onwards, in the Kuznetsk metallurgicheskiy kombinat (Kuznetsk Metallurgical Combine) (KMK) from 1950 onwards. "Elektroprivod" jointly with "Azovstal'", the DO TPEP (Dnepropetrovsk Division of Tyazhpromelektroprojekt), the OF SKBIM (Odessa Branch of the Special Design Office for Experimental Machinery) jointly with the zavod im. Starostina (imeni Starostin Works) have worked on this problem since 1954-1955. The automation systems of KMK and UPI-NTMK have been in operation for some time. The authors deal with the subject matter under the following chapter headings: the programme of loading the charge materials; features of loading charge materials;

Card1/2

An Analysis of Systems of Automation of Scale Cars SOV/133-59-1-2/23

arrangement of the programming apparatus; command equipment and equipment for fixing the weight of the materials; automation of the transportation; comparative analysis of 5 automation systems, one of which is available in 2 variants (table, p 7). The TsKB "Elektroprivod" system is considered to be the most complicated in respect of the quantity of equipment required but best as regards its technological potentialities. The most simple system in respect of equipment is the KMK system; the technological potentialities of this system are somewhat lower than those mentioned above. The most serious disadvantage of this system is the low accuracy of weighing and a complicated programming of collecting the burden. The other systems discussed are considered to be inferior. There is 1 table. P.D. Pesin, N.N. Podkanter and N.S. Fil' also participated in the work.

TITLE: The Development of Machine Science (Razvitiye nauki o mashinakh)

PERIODICAL: Vestnik Akademii nauk SSSR, 1958, ²⁸ Nr. 6, pp. 118-122
(USSR)

ABSTRACT: At the Institute of Machine Science of the AS USSR, the second All Union Conference on essential problems of the theory of machines and mechanisms took place from March 24 - 28. The task of this conference was the discussion of concrete results obtained by Soviet and foreign scientists in this field in the course of recent years, as well as to determine the main directions of the further development of this science. Besides Soviet scientists from various towns of the USSR, also scientists of the other peoples' republics took part. More than 80 reports and communications were heard. The first plenary meeting was opened by I. P. Bardin, Member, Academy

Card 1/5

The Development of Machine Science

SOV30-58-6-33/45

of Sciences. In his report A. A. Blagonravov dealt with the importance of machine science for solving the problems in the automatization of production processes. I. I. Artobolevskiy, Member, Academy of Sciences, gave a survey of the present stage of the machine and mechanism theory. N. G. Bruyevich, Member, Academy of Sciences, reported on the main trends in the development of the science of the accuracy in machine- and apparatus-building. V. Likhtenkel'dt characterized in short the stage of development of the theory of mechanisms in the German Democratic Republic, D. Manzheron reported on the works of Romanian scientists in this field. I. Shreyter (Czechoslovakia), Ya. Oderfel'd (Poland) and G. Kalitsin (Bulgaria) delivered short welcoming addresses. The work of the conference was carried out in 5 sections: analysis and synthesis of mechanisms; machine dynamics; theory of accuracy in machine and apparatus building; theory of automatic machines; theory of machine drives. Reports dealing with the preset control of metalworking machines met with great interest. At the end of the conference it was found that the research carried out is closely connected with the problem of automatization. It was

Card 2/5

The Development of Machine Science

SOV/ 30-58-6-33/45

noticed, too, that not all trends in machine theory show a uniform development. The most important problems for the future were outlined. Urgent problems concerning the method of teaching machine theory as a subject were discussed with the representatives of the Chairs of Universities.

The third All Union Conference on friction and wear in machines was organized by the Institute for Machine Science of the AS USSR in Moscow, and was held from April 9 - 15. It was attended by representatives of the ministries, the councils of national economy, the scientific research institutes, the universities and industrial enterprises of various cities of the USSR, as well as by the foreign scientists F. Dukati and E. Lekhner (Hungary), V. N. Konstantinesku and N. Tipey (Romania) and I. Sgon (Czechoslovakia). The conference was opened by A. A. Blagonravov, Member, Academy of Sciences. Further reports were delivered by:
1) Ye. M. Gut'yar on the present trends in the development of the theory on hydrodynamic lubrication.

Card 3/5

The Development of Machine Science

SOV/30-58-6-33/45

- 2) G. V. Vinogradov on some new problems in the field of lubrication and lubricating materials.
- 3) B. V. Deryagin on modern lubrication problems.
- 4) I. V. Kragel'skiy on the development of the sciences of dry friction.
- 5) M. M. Khrushchov on modern trends in the development of the science of wear and resistance to wear.

The work of the conference took place in 5 sections: hydrodynamic theory on lubrication and sliding surfaces; lubrication and lubricating materials; dry friction and limit friction; wear and resistance to wear; friction and antifriction materials. The conference expressed the wish that a national committee on friction and wear in machines be formed. The necessity of working out a terminology in the field of friction and wear was stressed. At the Universities for Machine Building a course of lectures on friction, wear and lubrication of machines is to be introduced. It was also suggested to establish branches of the seminary, of the Institute of Machine Science dealing with this field

AUTHOR: Pruzhanskiy, L. Yu. 129-58-5-4/17
TITLE: On Calculating the Deformation of Bimetallic Bushings
During Stamping (K raschete deformatsii bimetallicheskikh
vkladyshey pri stampovke)
PERIODICAL: Metallovedeniye i Obrabotka Metallov, 1952, No. 5,
pp. 15-16 (USSR)

ABSTRACT: After stamping of blanks of thin walled bimetallic bushings for automobile engines, the diameter in the division plane will be larger or smaller than the diameter of the die in which the stamping is carried out. Thus, in case produced blanks made of steel strip clad with babbitt the diameter increases; however, during experimental production of bushings made of bimetallic rolled strip consisting of a steel base and a plastic aluminum alloy, it decreases. From the technological point of view only a certain increase in the diameter is permissible but not a decrease. Literature does not contain formulae for determining the elastic deformation of a bimetallic bushing after stamping and, therefore, in this paper an attempt is made to calculate approximately the deformations of bushings after stamping and also the residual stresses Card 1/3 occurring in such bushings. The process of stamping of

129-58-5-4/17
On Calculating the Deformation of Bimetallic Bushings During
Stamping

bushings is considered as one taking place under conditions of uniaxial stress state without taking into consideration the widening during upsetting, external friction and the influence of the speed of impact on the

APPROVED FOR RELEASE: 06/15/2000 CIA-RDP86-00513R001343420007-
assumed that the change in the shape of the blank consists purely of plastic bending without hardening until the blank assumes the same radius as the die and this is followed by plastic upsetting at the face which is uniform along the width of the blank. The calculations are based on the diagrams of the virtual stresses during static tension which was assumed as being the same during compression and tension. If the geometrical dimensions of the blank and the mechanical characteristics of the materials of the bimetal are known, it is possible to calculate by means of the derived equations, Eqs.(3-6), approximately the change in the radius of curvature of the bushing and the residual stresses occurring in it after stamping. If the change in the radius of curvature of the blank after stamping is known, the residual stresses Card 2/3 can be calculated by means of Eqs.(2), (4), (5) and (6)

129-58-5-4/17

On Calculating the Deformation of Bimetallic Bushings During
Stamping

which are given in the paper. Verification has shown that for steel-aluminium blanks the radius should decrease, whilst for the steel-BT babbitt combination the radius should remain unchanged or increase. These results are confirmed by practical experience.

There are two figures.

Calculating internal stresses in thin-walled bimetallic specimens

SOURCE:

Akademiya nauk SSSR. Institut mashinovedeniya. Treniye i iznos v mashinakh, v. 14, 1960, 240 - 246

TEXT: A method is demonstrated of determining the internal stresses in thin bimetallic plates (steel and plastic bearing material) by elimination of small layers of the material of the same plate, first from the outer part and then from the inner part. The method of calculation is based on the procedure developed by N.N. Davidenkov, but to determine the internal stresses in the bearing material, the stresses in this material, caused by the previous removal of the layers of the steel base, are taken into account. It is stated that this method eliminates the deficiencies of the original method, as the determination of the internal stresses in both materials is carried out successively on the same specimen. There are 2 figures.

TITLE: Friction tests of teflon

SOURCE: Plastmassy kak antifriktionnyye materialy. Inst. Mashinoved.
AN SSSR. Moscow, Izd-vo AN SSSR, 1961, 74-79

TEXT: The article presents data obtained in friction and wear tests of teflon on steel at a constant load and at a gradually increasing load, and under conditions of dry friction and copious lubrication with B-2 (V-2) spindle oil. For this purpose, an Amsler test machine, modified for testing plastics, was used. The tests for friction and wear were conducted with segment-shaped teflon specimens and a short steel shaft; a 0.13-mm-thick film of teflon was also used for the friction tests. The plastic segments were held in a self-adjusting ball holder. Wear tests without lubrication showed that the wear of teflon varies in direct proportion to the duration of the test at a given load. The wear products had the form of flakes. Reduction of the thickness of the specimen as a result of the wear was accompanied.

Card 1/2

Friction tests of teflon

as in the case of the tests with lubrication, by thickening, so that the specimen assumed the shape of a trapezium. Under these conditions, but without lubrication, the mean friction factor was 0.20-0.25. Conclusions: (1) The friction factor in dry tests at specific loads from 4.2 to 34.1 kg/cm^2 and a sliding velocity of 0.37 m/sec was 0.20-0.25; (2) The observed regularity of wear in dry friction in the load range 4.2- 34.1 kg/cm^2 is analogous with the wear process of metallic bearing materials, i.e. the wear is directly proportional to the specific load and the length of the friction path; (3) The thickness of teflon specimens has a great effect on the permissible load, which is due to the low heat conductivity and low mechanical strength of this plastic. A thin film of teflon applied to metal bears the highest load; (4) In laboratory experiments with a 0.13 mm film of teflon on a steel base, the maximum possible specific load was over 200 kg/cm^2 at a sliding velocity of 0.37 m/sec when V-2 spindle oil was used as a lubricant. There are 6 figures and 2 tables.

TEXT: In determining residual stresses in a bimetallic plate by the usual method of successive etching of layers there appears a great inaccuracy if the elastic modulus of the layer is much smaller than that of the basic material. This takes place e.g. in the coating of steel with a soft bearing alloy, when the deflections in etching the coating are small and do not allow accurate measurement. The author offers a more rational method, when initially for greater thickness the plate is etched on the side of the steel base and then when etching the soft layer, the deflections due

TITLE: Flexure measurements during determination of internal stresses
in thin-walled specimens

PERIODICAL: Zavodskaya laboratoriya, v. 27, no. 9, 1961, 1138-1139

TEXT: A contactless method for flexure measurements of plates is proposed. The flexure is determined on the basis of changes in form of an originally straight-lined scratch, occurring during the removal of metal layers. The front of the specimen is scratched in the place of the future bend. A ПМТ-3 (PMT-3) device is used for scratching the specimen and for determining the maximum flexure. First, an accurate surface plate is mounted on the frame of the device, parallel to the axis of longitudinal displacement of the frame. Next, the indenting tool is lowered onto the front of the specimen, an indentation developing thereby. This is the start of the scratch. The frame is now moved steadily in one direction, the distance having to be smaller than the length of the specimen (10-12 mm). The straightness of the resulting scratch as well as its change in form due to Card 1/2

S/032/61/027/009/008/0-9

B117/B101

Flexure measurements during

the removal of layers are determined along the specimen in intervals of 0.5 mm on the eyepiece micrometer. For this purpose, the frame with the specimen is displaced longitudinally. The intersection of the eyepiece-micrometer crosshairs coincides with the center of the scratch, or with one of their sides. The position of the scratch perpendicular to the surface plate edge is determined. Measurement results are the more accurate, the narrower the scratch and the more pointed its edges when emerging to the surface. The method proposed was used for determining the flexure of a bimetallic plate. It consisted of a steel base with a thin aluminum alloy coating. The total thickness of the specimen was ~2 mm in the flexure plane. The specimen was 10 mm wide and 20 mm long. The scratch must be protected from damages during removal of the layers. Measurements should be made at constant temperature of the medium. There is 1 figure.

BY THE METHOD OF HARMONIC EXCITATION IN QUARTZ

M.M. Pruzhanskiy

Radiotekhnika, Vol. 11, No. 12, 15-27 (1956). In Russian.

The development of methods relating to the problem of direct stabilization of v.h.f. oscillators using quartz crystals is reviewed. Several systems are suggested where the static capacitance of the quartz is compensated by an inductance; bridge methods which permit high-order harmonic excitation are also considered and their circuits given. The methods of harmonically excited oscillators, including those in which the static capacity is not compensated, are classified and compared.

TITLE:

Bridge Circuits of Quartz Harmonic Vibration Generators
(Mostovyye skhemy garmonikovykh kvartsevykh generatorov)

PERIODICAL:

Radiotekhnika, 1958, Vol. 13, Nr 6, pp 29-46 (USSR)

ABSTRACT:

The analysis of the operation of bridge circuits of quartz harmonic vibration generators is dealt with. The analysis of the operation of compensation circuits of quartz harmonic vibration generators will be dealt with by a separate article. The analysis was based upon the quasilinear method. This made it possible to describe the results obtained by the investigation in a simple and comprehensive manner. As shown (Ref 4) this method can be applied not only for the determination of the amplitude (with an accuracy that is considered satisfactory in practice), but also for the determination of the frequency of the oscillations produced in the quartz generator. The theory developed here serves as a basis for the calculation of conditions for the determination of the amplitude and frequency of the oscillations produced. It explains the influence exercised by the modification of circuit parameters upon the amplitude and the aforementioned

Card 1/3

Bridge Circuits of Quartz Harmonic Vibration Generators

frequency in the case of quartz harmonic vibration generators with inductive-capacitive and purely capacitive bridge in the feedback circuit. On the strength of the results obtained by the analysis and the data given in tables the following was established: 1.) In bridge circuits of quartz harmonic vibration generators the frequency of the oscillations produced is equal to or nearly equal to the frequency of the continuous quartz resonance, which entails a high degree of fixing ability and therefore also frequency stability. 2.) In the circuits Nr 1 and 4 the oscillatory circuit is equivalent to the capacitive resistance ($\operatorname{ctg} \varphi$ equivalent < 0) and in Nr 2 and 3 to the inductive resistance ($\operatorname{ctg} \varphi$ equivalent > 0). 3.) Circuits Nr 1 and 4 make it possible for the generator to operate with the frequency of continuous resonance. 4.) In the circuits investigated transition from the excitation of a mechanical harmonic vibration of the quartz plate to others by means of a modification of the tuning of the circuit condenser is brought about without changing the tuning of the bridge elements, which determines the properties of the circuit domain. 5.) A purely oscillatory mode of operation of generators Nr 1 and 2 is warranted at values $\Delta \geq 0$ and of Nr 3 and 4 at values $\Delta \leq 0$. Δ is a dimensionless quantity and

Card 2/3

Bridge Circuits of Quartz Harmonic Vibration Generators

108-13-6-3/11

characterizes the extent of deviation from bridge equilibrium.
6.) The amplitude of the oscillations produced, which is characterized by d_i , is inversely proportional to the quartz resistance r_q , with conditions otherwise remaining the same. The lower r_q in the excited harmonic vibration, the greater the amplitude of oscillation. 7.) The ratios obtained here hold both in the case of a quartz excitation with basic frequency and also in the case of one with harmonic vibrations. There are 7 figures, 7 tables, and 4 references, 4 of which are Soviet.

MEASUREMENT & TEST GEAR

"Equivalent Electric Parameters of Quartz Plates Excited at Higher Harmonics", by M.M. Pruzhanskiy, Radiotekhnika, No 8, August 1957, pp 42-53.

The authors gives a description and the theoretical analysis of two independent methods of measuring the equivalent parameters of quartz operating at higher harmonics. The first method involves the substitution of the quartz crystal in an oscillating circuit, and the second involves a resonant method with the aid of a Q meter. The results of the measurement of the quartz parameters are given. It is shown that the quality of the quartz first improves with increasing number of harmonics, reaches a maximum, and upon further increase in the number of harmonics it begins to give poor performance. Refers to standard works by Vigoureux, Cady, and Mason.

TITLE: Equivalent Electric Parameters of Piezoquartz Plates which are
Excited by Harmonic Oscillation (Ekvivalentnyye elektricheskiye
parametry p'yezokvantsevykh plastin, vozbuздayemykh na
garmonikakh)
PERIODICAL: Radiotekhnika, 1957, Vol 12, Nr 8, pp 42-53 (USSR)

ABSTRACT: A description and a theory of two independent measuring methods for the measuring of equivalent quartz parameters are given. According to the first method, quartz is replaced by its equivalent, and in the case of the second method the resonance process for measuring the parameters of quartz by means of a Q-meter is applied. The measuring results admit of the following conclusions: 1.) The values of the blind parameters agree with the data of the theory of the odd-harmonic crystal.
2.) The values of effective parameters, on the other hand, do not agree with those of the aforementioned theory, because the latter does not divide up the frictional component F among individual components (interior friction, friction in the surface layer, losses to acoustic radiation, friction on places where parts are fastened, etc.). The measuring results show that at first the quality of quartz rises with the ordinal number of the harmonic oscillations, attains its maximum, after which,

3rd, 5th and 7th harmonics. They also give spectrograms for three of the types. Detailed conclusions are drawn about the behavior of the various resonators, their suitability for use in various applications (in particular, the possibility of using plano-convex resonators excited at the third harmonic in oscillators without tuned circuits), and the directions in which development is needed. The treatment is empirical, and the authors regret the lack of any suitable theory for the oscillation of these resonators. They thank V.A. Romanov and M.D. Katsenel'son for co-operation. TOPIC: Investigating the existing methods of measuring per-
meability of toroidal samples.

SOURCE: Zhurnal Russkogo Fizicheskogo Instituta imeni A. S. de Gaja, 1961, No. 1, p. 101. Chernikov, v. 16, 1961. Voprosy maglicheskoy
elektroniki, 90 - 95.

TEXT: The authors measured inductance of toroidal ferromagnetic
samples (inductometer's note: material not specified, probably fer-
rite) using a μ -meter at frequencies of 1 - 5 Mc/s. They found that
the usual formula for calculation of permeability,

$$\mu = \frac{L_1 \cdot 10^4}{4\pi w^2 s} \quad (2)$$

Chart 1

Investigating the existing ...

where L is the inductance, l is the mean length of the toroid, w is the width of turns and S is the cross-section of the toroid, was inaccurate because the value of α depended strongly on the number of turns and whether all the turns were distributed uniformly over the toroid or concentrated in one place. A better value of α was obtained from $\alpha_2 = L_1 L_0$, where L_1 is the inductance of a coil with a ferromagnet in it and L_0 is the inductance of the same coil without a core. Improved accuracy was obtained by using a large number of turns and avoiding tapping corrections. There are 4 figures and 3 references: 2 Soviet-bloc and 1 non-Soviet-bloc. Law of increase of electric conductivity in dielectrics in strong electric fields. V. I. Pruzhinskii-Ganayevskaya. J.

The increase of the dielectric constant of dielectrics with increasing electric field is observed by T. Iizumino-Arai-Sasaki, *J. Appl. Phys.*, **11**, 625 (1940).

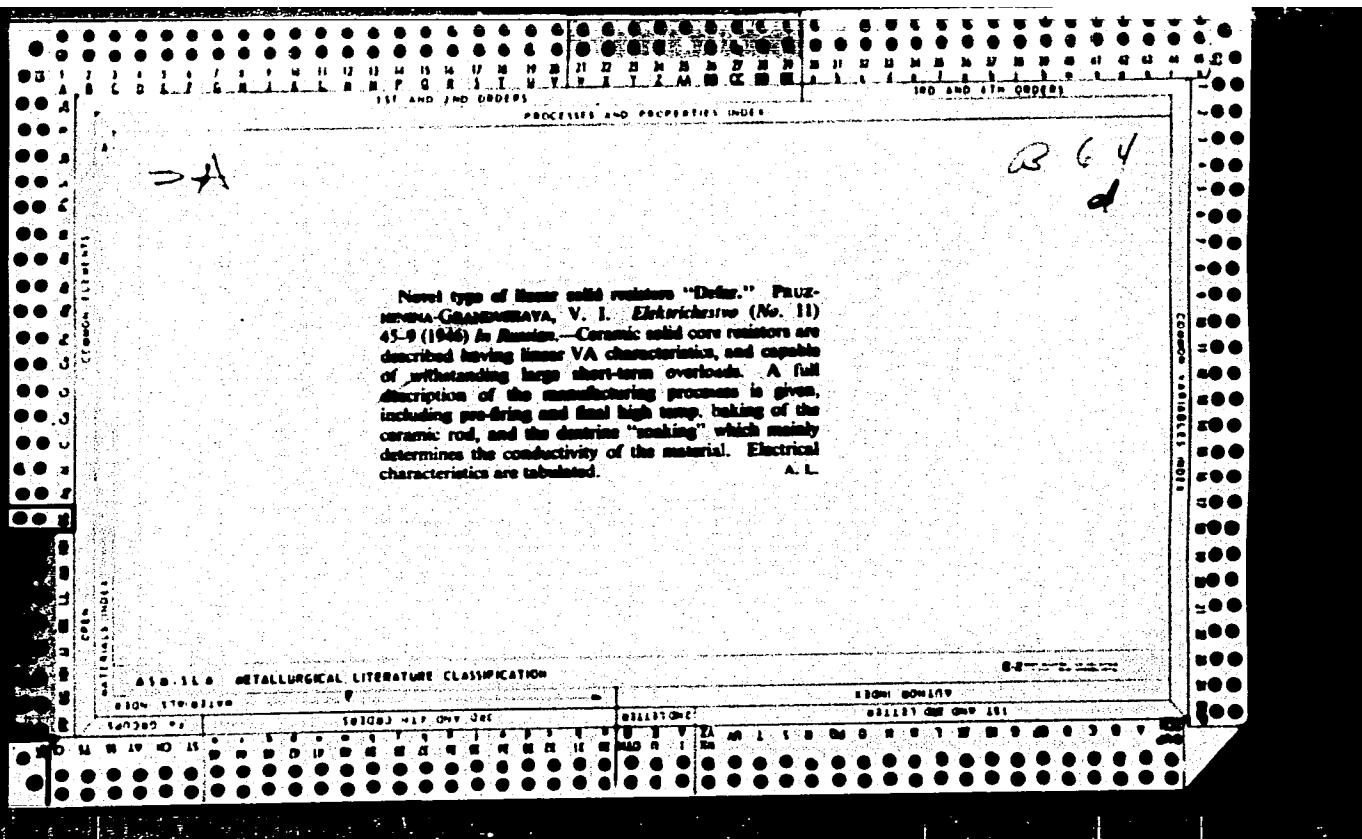

The increase of the elec. cond. of dielectrics with increasing fields according to Poole (C. A., 10, 375) is given by $\sigma = \sigma_0 e^k$, in which $\log \sigma$, plotted against E (elec.-field strength) is a straight line, (k and σ_0 are empirical consts.), and according to Frenkel (C. A., 33, 1810) from the idea that the elec. field facilitates thermal ionization, by $\sigma = \sigma_0 e^{k/T}$, where σ_0 is the cond. in weak fields, and $e = \sqrt{eV/kT}$ (where e = electronic charge, V = dielec. const., k = Boltzmann's const., and T the abs. temp.). From this formula, $\log \sigma$ gives a straight line when plotted against \sqrt{E} . Data from the literature show that the 2nd formula is correct in a larger interval of E , and the deviations from linearity are smaller than with the 1st formula. The variation of ϵ with temp. is correctly represented by Frenkel's formula, but the abs. value of ϵ calcd. from it is false. This is probably due to the effect of small amounts of impurities in the dielectrics that favor ionization. The exptl. values of ϵ for mica at 60° and 263° are, resp., 7.15×10^{-4} and 5.10×10^{-4} , compared with the theoretical figures of 5.10×10^{-4} and 3.75×10^{-4} .

Cause of the nonlinear current-voltage characteristic of silicon carbide. V. I. Pruzhinnina-Granovsaya. Zhur. Tekh. Fiz. 19, 100-TK(1973).—A decision whether the nonlinear increase of the elec. cond. σ of SiC with increasing voltage V , observed from a certain crit. field strength E_c , is due to the field in the blocking layer reaching E_c up, or to penetration of carriers from the bulk of the semiconductor into the blocking layer, through diffusion facilitated by the applied field, was sought by measurements of the Hall effect and of the relative change of the elec. resistance, $\Delta R/R$, produced by a magnetic field. Samples of black and of green SiC were used; the former had a steeper current-voltage curve. The dimensions of the samples were 10-20 mm. in length, 5-10 mm. in width, and 2-5 mm. in thickness. The Hall voltage V_H is a linear function of the magnetic field up to 22,000 G. The carrier concn. n was detd. from the Hall const. $R = \pm(3\pi/8)/en$, for a low-resistance green SiC, with hardly any blocking layer; from n , the velocity of the electron $v = I/en$, and the mobility $u = g/V$, where I = (1.5-2) $\times 10^{-9}$ A. The mobility u is of the order of 1 cm./sec., V in (v/cm.), and n of the order of $10^{17}/cm^3$. In nonlinear black SiC samples, n was independent of V in the transmitting direction, but decreased somewhat with V in the blocking direction; the order of magnitude of n is normal, i.e. the cond. is electronic, pos. (p-type) cond. was found only in samples of nonlinear green SiC. The $\Delta R/R$ effect increases with V . In the same V range, the increase of $\Delta R/R$ is steeper with the more definitely nonlinear black SiC. The $\Delta R/R$ effect decreases slightly with increasing temp. Between room temp. and 100-200°, R decreases linearly with $1/T$; green SiC has the greater temp. coeff. The $\Delta R/R$ permit. detn. of the mobility u^* in the blocking layer, and give the values of $n^* E^*$, where E^* is the field in the blocking layers; under the legitimate assumption that practically all the field is concd. in the blocking layer, $V = E^* d$ (where d is the sum of the thicknesses of the 2 blocking layers), and n^*/d as a function of V characterizes the dependence of n^* on V . In black SiC, u^* increases by a factor of approx. 2.5 between $V = 0.2$ and 1.8 v. In the weakly nonlinear green SiC, u^* increases with V much more slowly, more markedly in the transmitting than in the blocking direction. Inasmuch as u^* can increase with V only in strong fields, it is evident that a "Pauli" effect must take place in the thin blocking layers, and that this effect is accompanied by an increase of u^* with the field. The order of magnitude of u^* is 10^{-10} , i.e. the same as in other semiconductors, Cu₂O or TiO₂.

In the V range in which u^* increases by a factor of 2.5, u^* increases by a factor of 6.7. Consequently, there must be, along with an increase of u^* , also an increase of n^*/d . It can be that the total increase of n^* is due to an increase of n^* in one of the 2 blocking layers, and an increase of n^* in the other. The apparent slight decrease of u^* with n^* in the other, is a secondary effect, due to a redistribution of the potential drop between the bulk and the blocking layers. Actually, u^* seems to be independent of the temp. N. Tlou

ampere characteristic of carborundum. V. I.
PRUZHININA-GRANOVSKAYA. *J. Tech. Phys., USSR,*
15, 103-10 (Jan., 1950) *In Russian.*

It was determined that the electrical conductivity
of the blocking layer of carborundum increases with
the potential, due to the increase in mobility of elec-
trons in the blocking layer, which is one of the reasons
for the Poole effect. It was shown that the electron
mobility of the blocking layer increases at the expense
of the electron concentration.

CA

Electric properties of silicon carbide. L. I. Ivanov, V. I. Pruzhina-Ganovskaya, and I. V. Chernina. Zhur. Tekh. Fiz. 21, 1050-60 (1951).—The elec. resistance ρ of the blocking layers of different prepn.s. of SiC, in the form of powder of narrowly homogeneous grain size of 0.46 mm., under the uniform pressure of 54 kg./sq. cm., was measured in the elec. field strength range $E = 0.6-60$ v./cm. Except in low E (< 2 v./cm.), $\log \rho$ decreases nearly linearly but slowly with increasing E . The order of magnitude of ρ for different samples, under identical conditions of pressure and grain size, varied between 1.8×10^4 and 8.3×10^9 ohm. cm. At the same time, the capacity C of a layer of powder of 1 sq. cm. cross section, 1 mm. high, was nearly the same for all prepn.s., about 11 microfaradays. As $1/C$ is proportional to the thickness of the blocking layer, and on the assumption that the dielec. consts. of the different samples cannot be very much different, it follows that the observed very large differences of ρ from one sample to another are not due to differences of thickness of the blocking layers. The elec. cond. σ of the bulk of the SiC was detd. by the temp. rise due to Foucault currents induced by a high-frequency magnetic field; σ falls linearly with increasing temp. (25-05°), i.e. the cond. of the bulk is metallic. The elec. resistance $1/\sigma$ of the bulk is of the order of 1 ohm cm., as against

10^4-10^9 for the resistance of the blocking layers, and there is no parallelism and no relation between the two. The non-linearity coeff. a of the current-voltage characteristic, defined by $U = cI^a$ (where U = voltage, I = current intensity, and c and a are const.s.), varies with the resistance (or with U at given I) in a different manner in different samples. The distribution curves of the breakdown potentials, i.e. the curves of the no. n of grains breaking down plotted as a function of the voltage U , pass through a max. at a certain U_m which varies from one sample to another, and increases with ρ of the blocking layer.

Title : Pulse Breakdown of Carborundum Grains and the Behavior of the
Grain Complex at Pulse Current Reaction

Periodical : Zhur. Tekh. Fiz, 25, 581-589, 1955

Abstract : The breakdown voltage of stopping layers of carborundum grains was
tested at pulse periods of 3 to 2600 microsec. The breakdown volt-
age was found to depend on the pulse period. It also has thermal
character. The plotted curves facilitated explanation of rules
governing the breakdown of nonlinear resistance. Three USSR and 3
foreign references.

✓ Effect of impurities on the electrical conductivity and the nonlinearity of silicon carbide. I. I. Ivanov and V. I. Przhinina-Granovskaya. Zhur. Tekh. Nauk. 26, 23-31 (1963). The powder was compressed in an insulated press die and subjected to elec. pulses of given duration. The volt-ampere characteristic $U = CI^{\alpha}$ was taken at pressures of 100-2000 kg./sq. cm. and at currents of 1 and 20 amp. $U_{1\text{amp}}$ and α change w/ pressure. From 650 to 1850 kg./sq. cm. U_1 decreases by 28% and α increases 1.06 times. With increasing grain size, the elec. cond. and α increase, in agreement with some theoretical considerations. Different "electrotech." and "abrasive" SiC powders were investigated. α increases in layers that are farther distant from the core in an Acheson oven (in all tests α varied between ~0.2 to 0.5). Fe⁺⁺⁺ and Cr⁺⁺ increase the cond. but decrease nonlinearity. Al⁺⁺⁺ increases nonlinearity. Addn. of Al to an otherwise stoichiometric SiC gives good "electrotech." SiC. S. Puksev

Comparison of experimental results with theories so far suggested for the mechanism of the non-linear characteristics of this type of resistor shows that none of these theories explains the observed phenomena correctly. Of special interest are the experimental data on current-carrying capacity and the progressive breakdown process of these resistors.

TITLE: Some Electric Properties of Boron-Silicon Carbides

PERIODICAL: Fizika tverdogo tela, 1959, Vol 1, Nr 10,
pp 1587 - 1591 (USSR)

ABSTRACT: Boron-silicon carbides (BSC) were burned in furnaces at $\approx 2000^{\circ}\text{C}$. End product: approximately 50-70 kg. Sample Nr 1, BSC-1 (composition: B_2SiC), is likely to be produced according to the reaction equation $2\text{H}_3\text{BO}_3 + \text{SiO}_2 + 6\text{C} = \text{B}_2\text{SiC} + 3\text{H}_2\text{O} + 5\text{CO}$, while BSC-2 (composition: $\text{B}_4\text{C} \cdot 2\text{SiC} = \text{B}_4\text{Si}_2\text{C}_3$) is probably formed according to the reaction equation $4\text{H}_3\text{BO}_3 + 2\text{SiO}_2 + 13\text{C} = \text{B}_4\text{Si}_2\text{C}_3 + 6\text{H}_2\text{O} + 10\text{CO}$. Results of chemical analysis of the two druse-shaped samples are given in table 1. For results of electric measurements see figure 1 (dynamic volt-ampère characteristics of BSC-1, BSC-2 and Si(samples)), figure 2 (volt-ampère characteristics of BSC-1, BSC-2 and SiC samples) and figure 3 (dependence of voltage on temperature of BSC-1,

BSC-2 and SiC samples at constant current). Analysis of the results permits the following conclusions: 1) The nonlinearity of BSC used in engineering is interior to that of SiC applied in electrical engineering. 2) The resistivity of the barrier layer of BSC is lower than that of the corresponding SiC layer, while the resistivity of thick BSC crystals exceeds that of thick SiC samples. The high resistivity of thick BSC grains allows to produce high-resistance volume resistors from them. They are virtually linear and may have great or small temperature coefficients. Results of measurement concerning the electric properties of BSC resistors will later be published. There are 3 figures, 2 tables, and 6 references, 4 of which are Soviet.

TITLE: Controlled Non-Linear Semiconductor Resistances¹⁵

PERIODICAL: Radiotekhnika i elektronika, 1960, Vol 5, Nr 6,
pp 1006-1008 (USSR)

ABSTRACT: The principle of controlling the parameters of a non-linear semiconductor resistance using a transverse electric field permits the development of a number of function-conversion circuits distinguished by simplicity, reliability and stability as well as by low cost. Such devices may be used for phase discriminators, modulators, voltage stabilisers, corrective networks with variable parameters, controlled voltage dividers, multiplier and divider circuits, automatic gain controls, oscillator frequency controls, etc. The authors have worked on this subject since 1957. Polycrystalline silicon carbide was used for these experiments. The properties are relatively stable in a wide temperature interval (-60 +50 °C) at frequencies up to 20 kcs. Four-electrode, six-electrode, and other configurations are described.

TITLE: A standard series of main parameters of valve and
tubular type lightning arresters (for discussion)

PERIODICAL: Referativnyy zhurnal, Elektrotexnika i energetika,
no.9, 1961, 38, abstract 9I 245. (Vestn. elektroprom-
sti, no.12, 1960, 27-31)

TEXT: The article proposes the classification of valve and
tubular lightning arresters into a standard series of main
parameters. Magnetic-valve arresters developed for 110-120 kV
are of improved protective characteristics, so permitting reduction
in impulse test voltages and also facilitating insulation of
transformers and equipment. In order to improve the technical and
economic characteristics of Soviet 220-500 kV transformers it is
necessary to improve the protection ratio of lightning arresters to
2.0 - 1.9 and of machine arresters to 1.8 - 1.9. On the basis of
analysis of the current standard for valve-type arresters, of a

Card 1/4

A standard series of main parameters.. S/196/61/000/009/038/052
E194/E155

draft standard for magnetic-valve arresters, and of the prospects of developing new arresters with improved protection, the following series of protection ratios is recommended for arresters rated from 3 to 500 kV: 3.3-3.1; 3.0-2.8; 2.6-2.5; 2.5-2.3; 2.2-2.1; 2.0-1.9; 1.9-1.8. It is recommended that the standard series of arresters rated from 3 to 220 kV should be arranged according to the parameters of the maximum value of short-circuit current interrupted in each voltage class, with an indication of the minimum permissible value of the ratio of highest to lowest short-circuit current interrupted. It is possible to increase the interrupting capacity of tubular arresters type PTB (RTV) by reinforcing them by a multi-layer winding of glass fibre cloth grade 3CTB-6 (ESTV-6) applied to the thin-walled arc-suppression tube, which is made of hard polyvinyl chloride plastic. In this way arresters have been developed for voltages of 35 - 110 kV and short-circuit currents of 20 kA. However, it is not yet technically possible to develop tubular arresters for voltages of 35 - 220 kV for interrupting short-circuit currents exceeding 30 kA, and coordinating gaps combined with automatic repeated reclosure of the lines are the recommended alternative.

Card 2/4

A standard series of main parameters.. S/196/61/000/009/038/052
E194/E155

A standard series of tubular arresters from 3 to 220 kV selected according to the maximum values of short-circuit current interrupted can be: 2.5; 5; 10; 20; and 30 kA effective. Here the minimum ratio of the maximum permissible short-circuit current to the minimum for tubular arresters of 3 - 6 - 10 kV should be 8; for those of 35 - 60 - 110 - 220 kV the recommended figure is 5. In conformity with the existing standard series of tubular arresters, the nomenclature **PTD**(RTF), RTV, and **PTBY** (RTVU) is applied to the new arresters in the range from 3 to 220 kV. They should be developed and manufactured for various voltages and ranges of short-circuit current interrupted, and each voltage class should be provided with fittings for mounting and recording operations. It is proposed to develop tubular arresters for voltages of 3 - 6 - 10 kV using cheap, strong and moisture-resistant materials, and to satisfy the demand for tubular arresters for 35 - 60 - 110 - 220 kV by types RTV and RTVU. The proposed classification will help to avoid duplication of manufacture of electrical equipment and will most conveniently satisfy the design organisations, operating companies and

industry in respect of range and parameters of protective devices. Tables are given indicating the nomenclature and main parameters of the valve-type and the tubular dischargers which are in production or will be produced.
